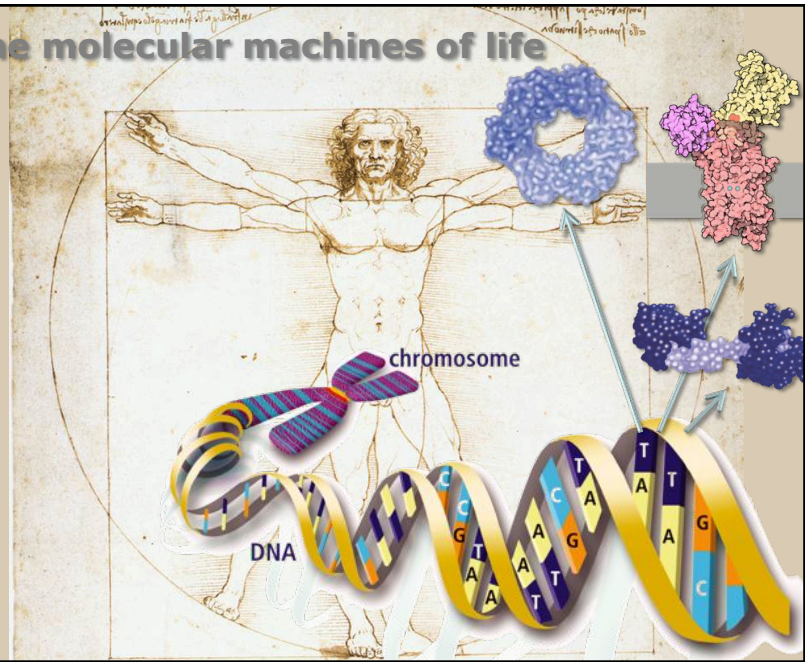
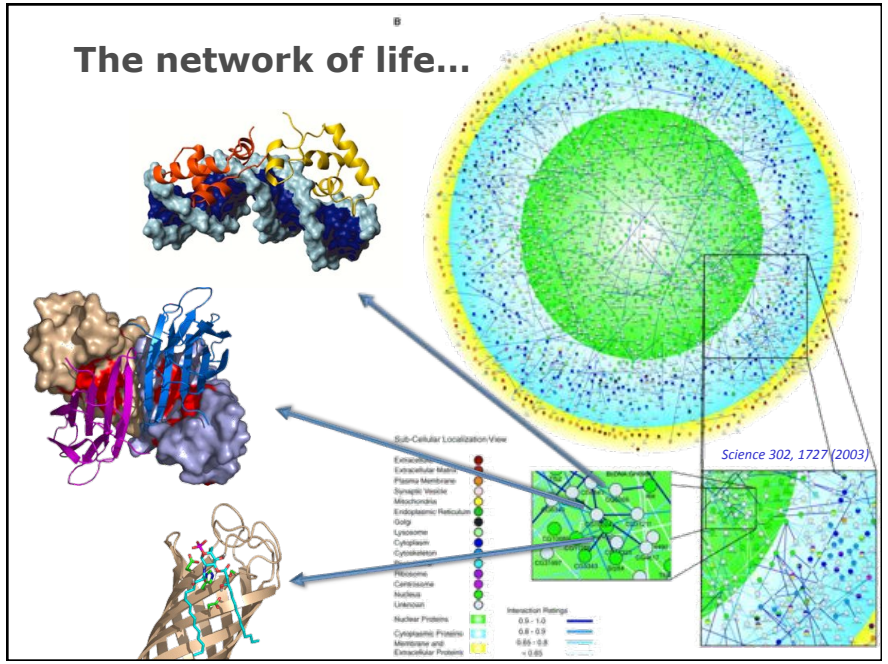
The molecular machines of life



The network of life…

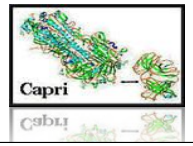


Science 302, 1727 (2003)

Study of biomolecular complexes

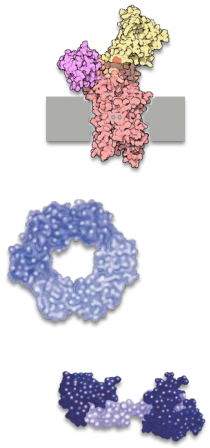
- Classical NMR & X-ray crystallography approaches can be time-consuming
- Problems arise with "bad behaving", weak and/or transient complexes!
- Complementary computational methods are needed!

→ "docking" prediction of the structure of a complex based on the structures of its constituents



"Critical assessment of predicted interactions"
http://capri.ebi.ac.uk

What can we learn from 3D structures (models) of complexes?



- Models provide structural insight into function and mechanism of action
- Models can drive and guide experimental studies
- Models can help understand and rationalize the effect of disease-related mutations
- Models provide a starting point for drug design

Data-driven docking

- There is a wealth of (easily) available experimental data on biomolecular interaction.
- When classical structural studies fail, these are however often not used and the step to modelling (docking) is most of the time not taken.
- These data can be very useful to filter docking solutions or even to drive the docking and thus limit the conformational search problem.

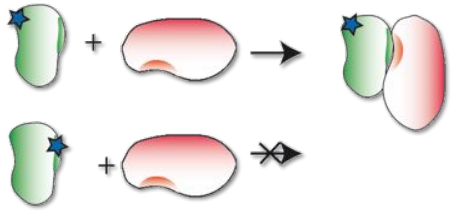
- SAXS & docking
- Conclusions & perspectives

Experimental sources:
mutagenesis



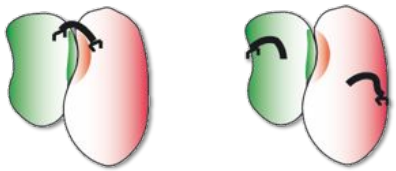
Advantages/disadvantages

+ Residue level information
- Loss of native structure should be checked

Detection

- Binding assays
- Surface plasmon resonance
- Mass spectrometry
- Yeast two hybrid
- Phage display libraries, ...

Experimental sources:
cross-linking and other chemical modifications



Advantages/disadvantages

+ Distance information between linker residues
- Cross-linking reaction problematic
- Detection difficult

Detection

- Mass spectrometry

Experimental sources:
H/D exchange

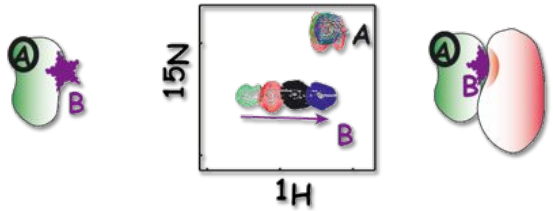
Advantages/disadvantages

+ Residue information
- Direct vs indirect effects
- Labeling needed for NMR

Detection

- Mass spectrometry
- NMR ^{15}N HSQC

Experimental sources:
NMR chemical shift perturbations



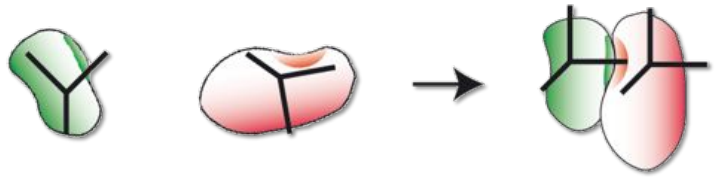
Advantages/disadvantages

+ Residue/atomic level
+ No need for assignment if combined with a.a. selective labeling
- Direct vs indirect effects
- Labeling needed

Detection

- NMR ^{15}N or ^{13}C HSQC

Experimental sources:
NMR orientational data (RDCs, relaxation)



Advantages/disadvantages

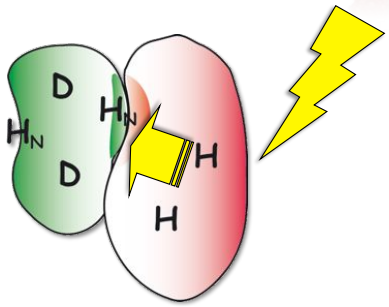
+ Atomic level
- Labeling needed

Detection

- NMR

Experimental sources:
NMR saturation transfer

Amide protons at interface are saturated
==> intensity decrease



Advantages/disadvantages

+ Residue/atomic level
+ No need for assignment if combined with a.a. selective labeling
- Labeling (including deuteration) needed

Other potential experimental sources

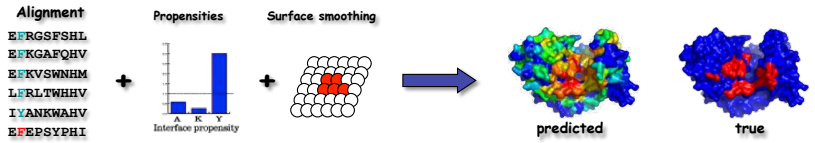
- **Paramagnetic probes** in combination with NMR
- **Cryo-electron microscopy** or tomography and **small angle X-ray scattering** (SAXS) ==> shape information

- Fluorescence quenching
- Fluorescence resonance energy transfer (FRET)
- Infrared spectroscopy combined with specific labeling
- …

Predicting interaction surfaces

- In the absence of any experimental information (other than the unbound 3D structures) **we can try to predict interfaces from sequence information?**
- **WHISCY:**

  WHat **I**nformation does **S**urface **C**onservation **Y**ield?



http://www.nmr.chem.uu.nl/whiscy

De Vries, van Dijk Bonvin. *Proteins* 2006

What is conservation?

- **Conservation occurs when residues are expected to mutate, but do not mutate, or much more slowly**
- **How to calculate conservation?**
  - Generate a sequence alignment
  - Calculate the expected mutation behavior
  - Calculate deviations from this behavior
  - Is there less change than expected?
- **The residue conservation score is the sum of all deviations from expected behavior**

How to calculate expected conservation?

AFRGTFSHL	AFRGTFSHL
EFRGSFSHL	EFEPSYPHI
Near identical sequences	**Different sequences**
No conservation	**Conservation**

Sequence distance **must be taken into account**

Residue mutation matrix example

- **"Four residue world": Ala, Asp, Glu, Trp**
- **Sequence distance: 1 % mutation**

	Ala	Asp	Glu	Trp
Ala	**99**	0.33	0.33	0.33
Asp	0.33	**99**	0.33	0.33
glu	0.33	0.33	**99**	0.33
Trp	0.33	0.33	0.33	**99**

Residue mutation matrix example

- Some residues mutate however faster than others

	Ala	Asp	Glu	Trp
Ala	98	0.67	0.67	0.67
Asp	0.33	99	0.33	0.33
glu	0.33	0.33	99	0.33
Trp	0.17	0.17	0.17	99.5

Residue mutation matrix example

- Some mutations are more likely than others

	Ala	Asp	Glu	Trp
Ala	98	0.67	0.67	0.67
Asp	0.17	99	0.67	0.17
glu	0.17	0.67	99	0.17
Trp	0.17	0.17	0.17	99.5

Residue mutation matrix example

- You can multiply the matrix by itself to generate distance specific matrices
  - E.g. result of 20 multiplications: 20 % mutation

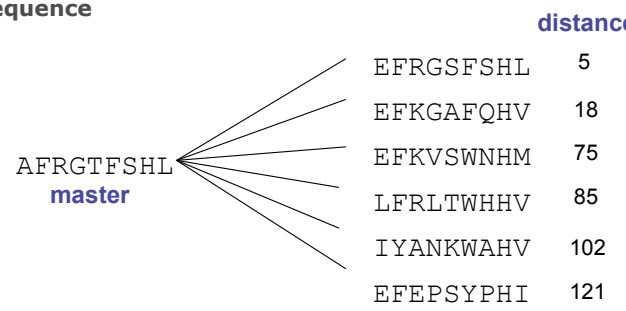
	Ala	Asp	Glu	Trp
Ala	65.96	11.35	11.35	11.35
Asp	2.84	82	11.74	3.42
glu	2.84	11.74	82	3.42
Trp	2.84	3.42	3.42	90.32

Residue mutation matrix

- Several of such matrices exist
- The best known is the Dayhoff (PAM) matrix (Dayhoff *et al.* 1978)
- This matrix is used in Whiscy

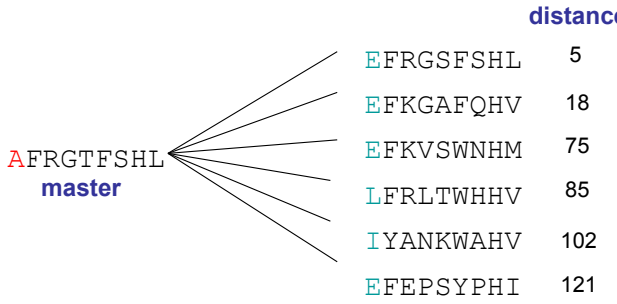
WHISCY calculation

- Take as input a 3D structure and a sequence alignment
- protdist (Felsenstein *et al.*) used to calculate the sequence distances
- WHISCY compares the master sequence to every other sequence

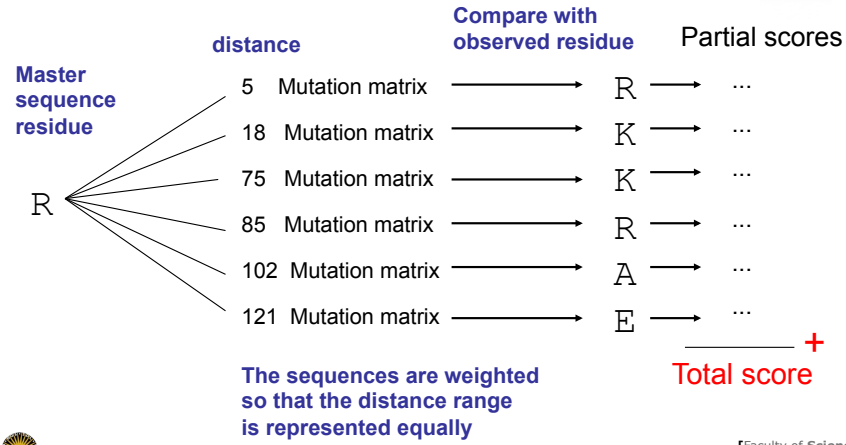


WHISCY calculation

- Each residue is scored independently



WHISCY calculation



Partial score

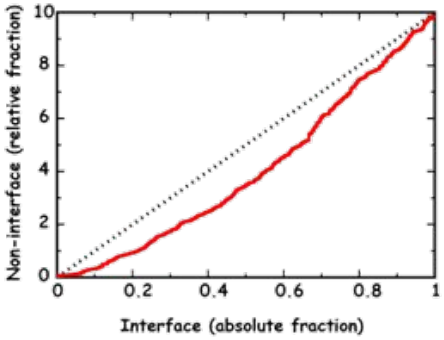
- The partial score is equal to the probability in the distance-dependent mutation matrix
- A correction factor corresponding to the sum of squares of all probabilities is subtracted
- This makes sure that the average score is zero
- WHISCY score > 0 indicates conservation

Testing WHISCY with known complexes

- **Benchmark of 37 protein complexes** (Chen *et al.* 2003)
- **Sequence alignments from the HSSP database** (Sander *et al*. 1991)
  - Some proteins were left out of prediction because of bad sequence alignments
- **Interface definitions by DIMPLOT** (Wallace *et al.* 1995)
  - Residues making contacts across interface (hbond + non-bonded)
- **Surface definition by NACCESS** (Hubbard & Thornton 1993) (15 % accessibility cutoff)

WHISCY raw performance

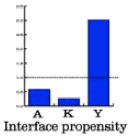
- Fraction of correct versus incorrect predictions for the benchmark



Improving the score using amino acid interface propensities

- Each amino acid has its own interface propensity (from analysis of 3D structures of known complexes):

$$\frac{\text{frequency at the interface}}{\text{frequency at the surface}}$$



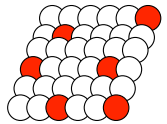
- **WHISCY score converted into a p-value and divided by the a.a. interface propensity**

Residue X: score → p = 0.10 → (/ 2.5) → p = 0.04 → higher score

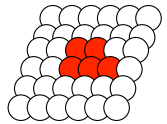
Residue Z: score → p = 0.10 → (/ 0.4) → p = 0.25 → lower score

Improving the score by surface smoothing

- Interface residues are not spread over the surface but form patches



unlikely interface



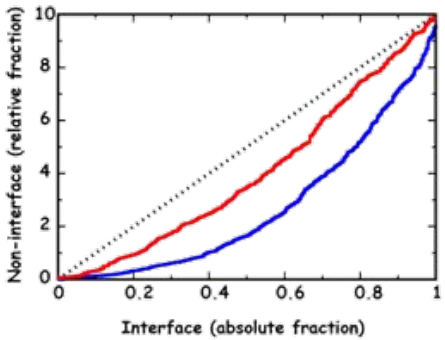
likely interface

- Take the scores of the neighbors into account:
  - Residues with high-scoring neighbors should get a bonus
  - Residues with low-scoring neighbors should get a penalty

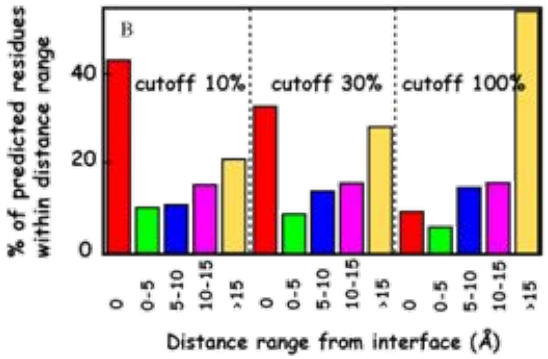
=> Scores are smoothed over a 15Å radius using a Gaussian or optimized step function

WHISCY optimized performance

- **Fraction of correct versus incorrect predictions for the benchmark**



Distribution of predicted interface residues as a function of their distance from the true interface



10% cutoff indicates the WHISCY cutoff resulting in 10% of the true interface predicted

Predicting interaction surfaces

- Several other approaches have been described:
  - HSSP **(Sander & Schneider, 1993)**
  - Evolutionary trace **(Lichtarge *et al.*, 1996)**
  - Correlated mutations **(Pazos *et al.*, 1996)**
  - ConsSurf **(Armon *et al.*, 2001)**
  - Neural network **(Zhou & Shan, 2001) (Fariselli *et al.*, 2002)**
  - Rate4Site **(Pupko *et al.*, 2002)**
  - ProMate **(Neuvirth *et al.*, 2004)**
  - PPI-PRED **(Bradford & Westhead, 2005)**
  - PPISP **(Chen & Zhou, 2005)**
  - PINUP **(Liang et al., 2006)**
  - SPPIDER **(Kufareva et al, 2007)**
  - PIER **(Porollo & Meller, 2007)**
  - SVM method **(Dong et al., 2007)**
  - ...

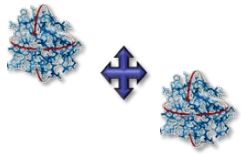
Docking

- **Choices to be made in docking:**
  - Representation of the system
  - Sampling method:
    - 3 rotations and 3 translations
    - Internal degrees of freedom?
  - Scoring
  - Flexibility, conformational changes?
  - Use experimental information?



Dealing with flexibility

- Flexibility makes the docking problem harder!
  - Increased number of degrees of freedom
  - Scoring more difficult
- Difficult to predict a-priori conformational changes
- Current docking methodology can mainly deal with small conformational changes
- Treatment of flexibility depends on the chosen representation of the system and the search method

Scoring

- **The holy grail in docking!**
- Depends on the representation of the system and treatment of flexibility
- Depends on the type of complexes
  - e.g. antibody-antigen might behave differently than enzyme-inhibitors complexes

Scoring

- Score is often a combination of various (empirical) terms such as
  - Intermolecular van der Waals energy
  - Intermolecular electrostatic energy
  - Hydrogen bonding
  - Buried surface area
  - Desolvation energy
  - Entropy loss
  - Amino-acid interface propensities
  - Statistical potentials such as pairwise residue contact matrices
  - ...
- Experimental filters sometimes applied *a posteriori* if data available (e.g. NMR chemical shift perturbations, mutagenesis,..)

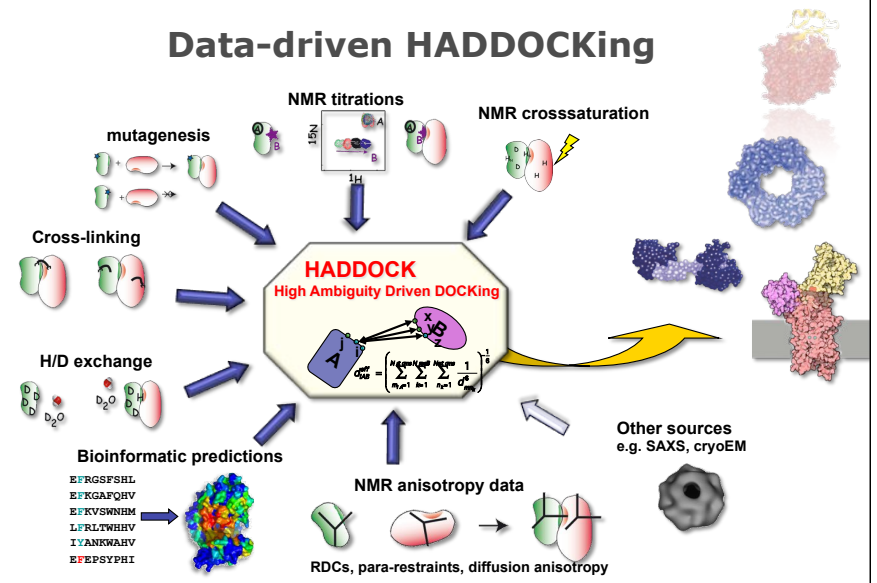
Data-driven HADDOCKing

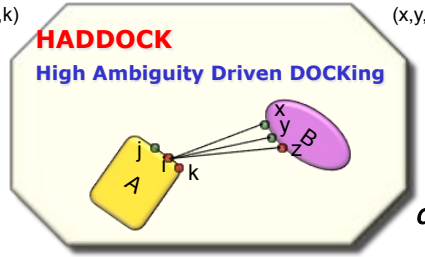


Dominguez, Boelens & Bonvin. *JACS* 125, 173 (2003).

Data-driven docking with HADDOCK

List of interface residues for protein A (i,j,k)

List of interface residues for protein B (x,y,z)



Effective distance d_{iAB}^{eff} calculated as

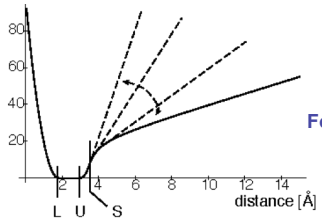
$$d_{iAB}^{eff} = \left(\sum_{m_{i\,A}=1}^{N\,at\,ams} \sum_{k=1}^{N\,resB} \sum_{n_k=1}^{Nat\,ams} \frac{1}{d_{mn_k}^6} \right)^{-\frac{1}{6}}$$

Ambiguous Interaction Restraint: (Nilges & Brunger 1991)
a residue must make contact with any residue from the other list

Different fraction of restraints (typically 50%) randomly deleted for each docking trial to deal with inaccuracies and errors in the information used

Ambiguous Interaction Restraints (AIRs)

- **Soft-square potential (Nilges) used to avoid large forces**

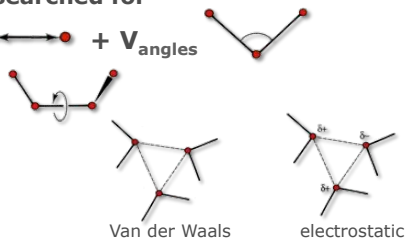


Force becomes constant >2Å violation

- **Different fraction of restraints (typically 50%) randomly deleted for each docking trial to deal with inaccuracies and errors in the information used**

Searching the interaction space in HADDOCK

- Experimental and/or predicted information is combined with an empirical force field into an energy function whose minimum is searched for
- $V_{potential} = V_{bonds}$ + V_{angles} + $V_{torsion}$ + $V_{non\text{-}bonded}$ + V_{exp}

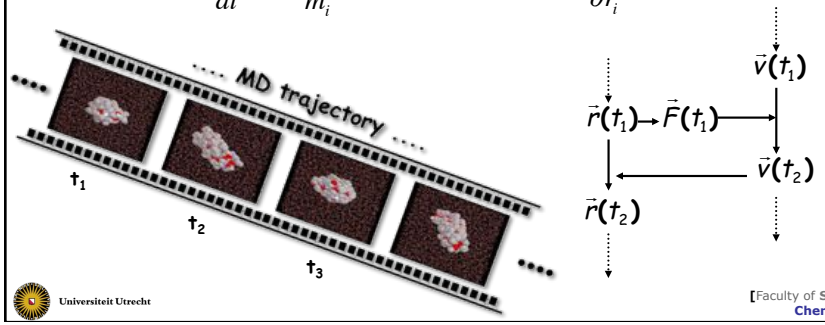


- Search is performed by a combination of gradient driven energy minimization and molecular dynamics simulations

Classical mechanics

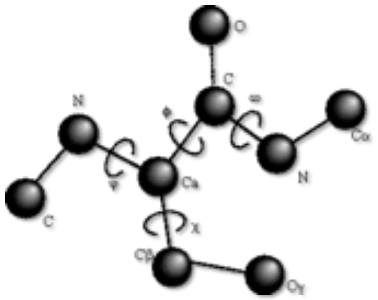
- Molecular dynamics: generates successive configurations of the system by integrating **Newton's second law**

$$\frac{d^2}{dt^2}\vec{r}_i = \frac{\vec{F}_i}{m_i} \quad \text{with} \quad \vec{F}_i = -\frac{\partial V}{\partial \vec{r}_i}$$

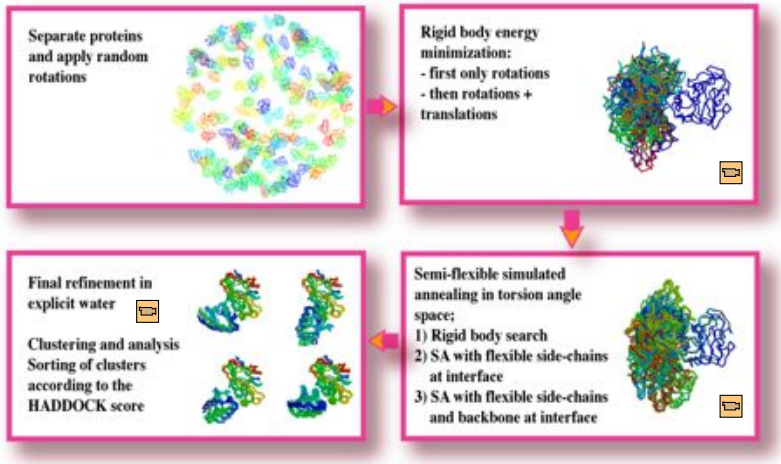


Torsion angle dynamics

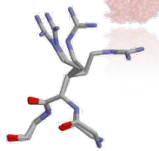
- dynamics time step dictated by bond stretching: waste of CPU time
- important motions are around torsions
- ~ 3 degrees of freedom per AA (vs $3N_{atom}$ for Cartesian dynamics)
- Available in DYANA, X-PLOR, CNS, X-PLOR-NIH



HADDOCK docking protocol

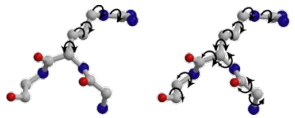


HADDOCK & Flexibility



- **Several levels of flexibility:**
- **Implicit:**
  - docking from ensembles of structures
  - Scaling down of intermolecular interactions

- **Explicit:**
  - semi-flexible refinement stage with both side-chain and backbone flexibility during in torsion angle dynamics
  - Final refinement in explicit solvent



Energetics & Scoring

- **OPLS non-bonded parameters** (Jorgensen, *JACS* 110, 1657 (1988))
- **8.5Å non-bonded cutoff, switching function, ε=10**
- **Ranking of based on HADDOCK score defined as:**

Rigid: Score = 0.01 E_{air} + 0.01 E_{vdW} + 1.0 E_{elec} + 1.0 E_{desolv} – 0.01 BSA

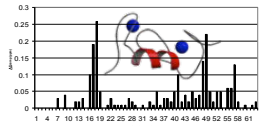
Flexible: Score = 0.1 E_{air} + 1.0 E_{vdW} + 1.0 E_{elec} + 1.0 E_{desolv} – 0.01 BSA

Water: Score = 0.1 E_{air} + 1.0 E_{vdW} + 0.2 E_{elec} + 1.0 E_{desolv}

- E_{air}: ambiguous interaction restraint energy
- E_{desolv}: desolvation energy using Atomic Solvation Parameters (Fernandez-Recio et al *JMB* 335, 843 (2004))
- BSA: buried surface area

The Not4 – UbcH5B complex

- **Not4: involved in the RNA polymerase II regulation. Contains a N-terminal Ring finger domain** (Hanzawa *et al.*, 2000)



- **UbcH5B: involved in the ubiquitination pathway**

Overview

HADDOCK's adventures in CAPRI

"Critical assessment of predicted interactions"

http://capri.ebi.ac.uk

- CAPRI is a blind test for protein-protein docking
- Usually 3 weeks for a predictions, 10 models can be submitted
- We participated to rounds 4 to 19 for a total of 27 targets
- For HADDOCK, we derived information to define AIRs from literature and bioinformatic predictions

Van Dijk et al. *Proteins* 2005; de Vries *et al. Proteins* 2007,2010

PagL

- Deacetylase (hydrolysis of acylesterbond)
- Activity found in S. typhimurium, B. Bronchiseptica and P. aeruginosa
- PagL homologues found in more than 10 bacterial species
- Crystal structure solved in Utrecht
- Only three residues conserved (Phe104, His126, Ser128)
- Site directed mutagenesis: serine hydrolase

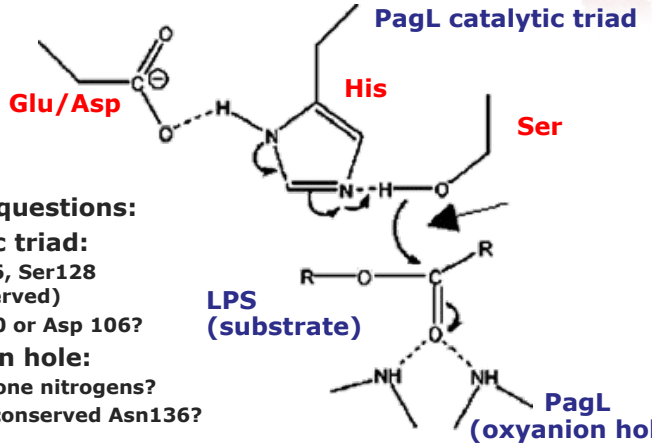
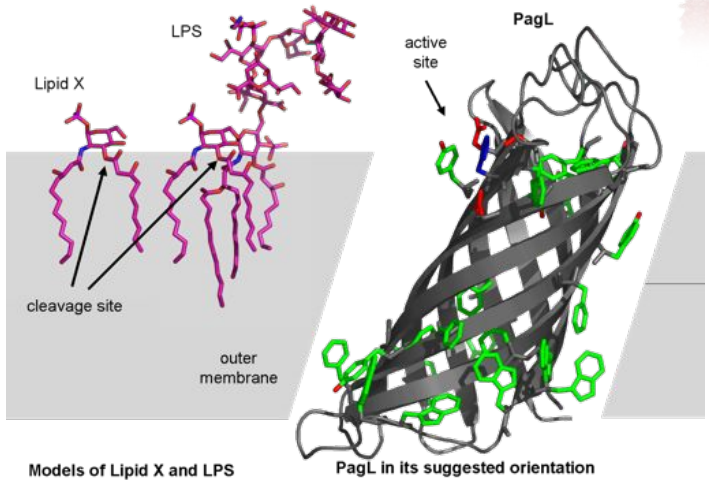
PagL: serine hydrolase mechanism



Still open questions:

- **catalytic triad:**
  - His126, Ser128 (conserved)
  - Glu140 or Asp 106?
- **oxyanion hole:**
  - backbone nitrogens?
  - semi-conserved Asn136?

Substrate recognition by PagL

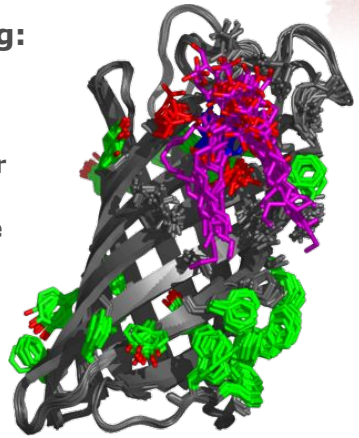


Models of Lipid X and LPS

PagL in its suggested orientation

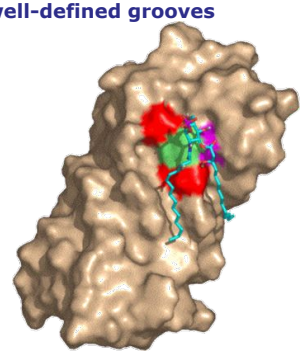
Lipid x docking onto PagL

- **Information for docking:**
  - **reaction mechanism**
    - carbonyl C of lipid x close to active site Ser of PagL
    - ester O of lipid x close to active site His of PagL
  - **hydrophobicity**
    - acyl chains of lipid x should be in the membrane



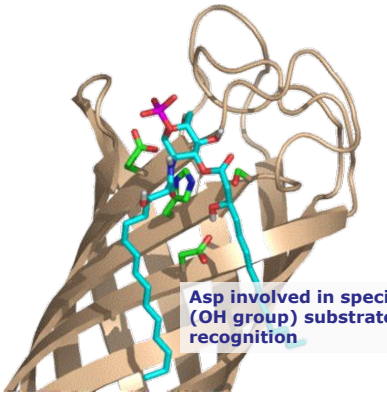
New insights from docking:

Lipid x acyl chains bind in well-defined grooves



HADDOCK best solution

Catalytic triad: Ser-His-Glu triad



Asp involved in specific (OH group) substrate recognition

PagL active site

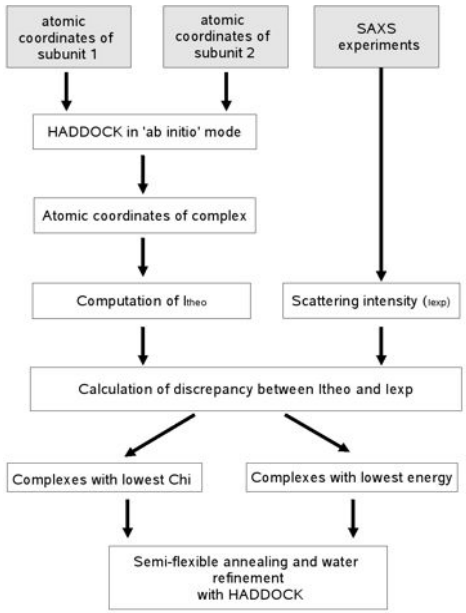
Combining SAXS and docking

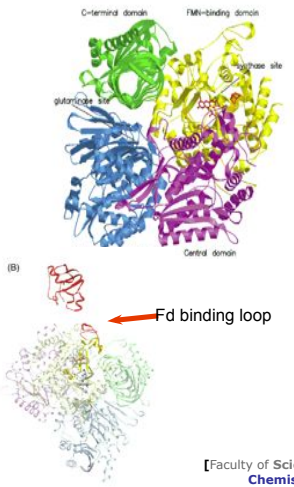
A possible strategy

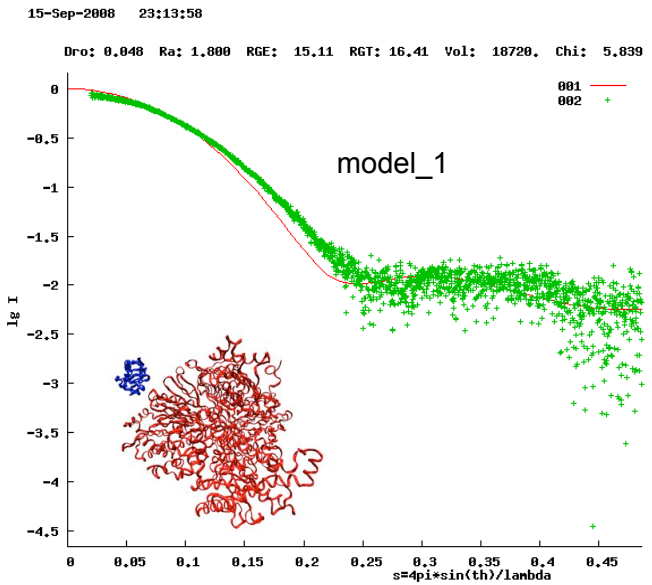
Crysol

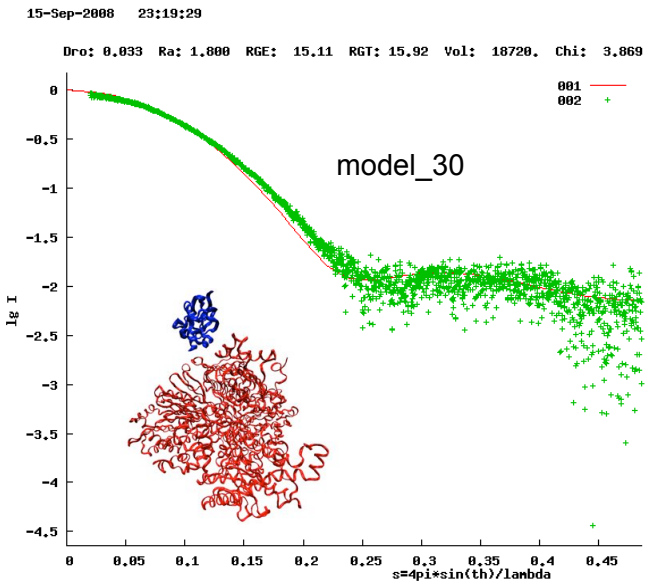


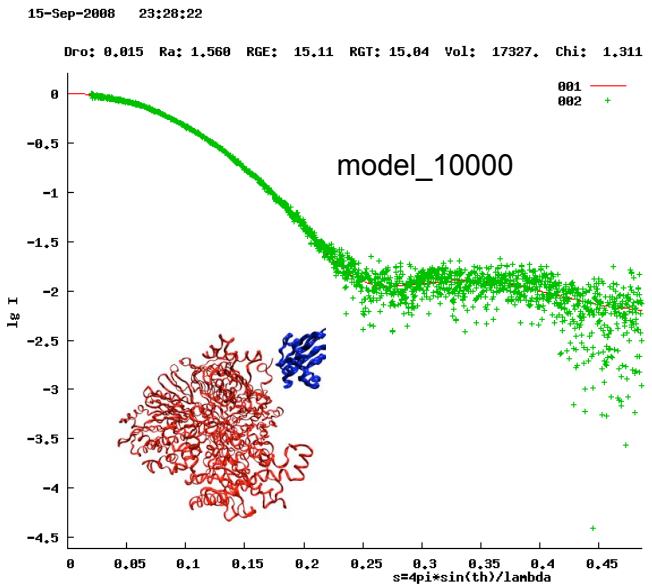
Combining SAXS & docking: one example

- GltS catalyzes the formation of two molecules of L-glutamate from L-glutamine and 2-oxoglutarate
- X-ray structures with substrate and inhibitor have been reported
- SAXS data on GltS and its physiological electron donor ferredoxin (Fd):
  - Suggests an equimolar (1:1) complex.
  - Model based on crystal structure of Fd:Fd-GltS(1:1) fits the SAXS data with χ^2 = 1.3

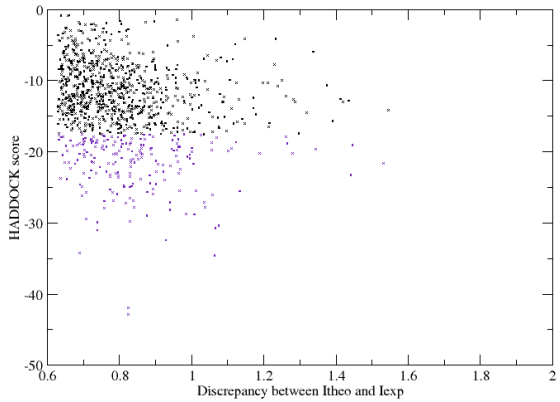




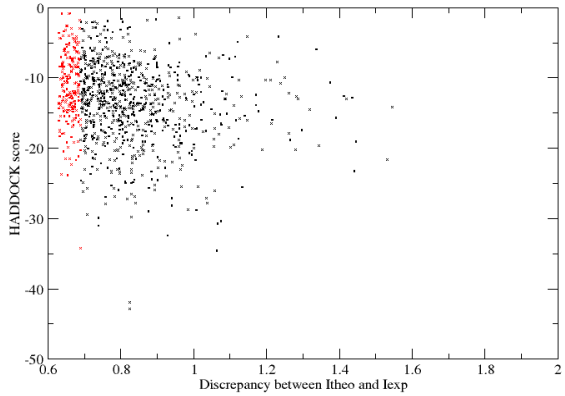




Selection based on HADDOCK energy



Selection based χ square



SAXS driven HADDOCK model (one of them …)

- (one of the) HADDOCK model selected based on χ2 has Ferredoxin close to the anticipated Fd-binding loop.
- Fits well to the experimental data (χ2 = 0.8)

χ^2 versus RMSD… a unique, well defined solution???

- **Conclusions & perspectives**

Conclusions & Perspectives

- **Data-driven docking is useful to generate models of biomolecular complexes, even when little information is available**
- **While such models may not be fully accurate, they provide working hypothesis and can still be sufficient to explain and drive the molecular biology behind the system under study**
- **Data-driven docking is complementary to classical structural methods**
- **Many challenges however remain:**
  - **Scoring**
  - **Predicting and dealing with conformational changes**
  - **Predicting binding affinities**
